TRAFFIC DECISION LAB / EARLY EXPERIMENT

Give unfinished queues a cost.

One additional term. The same revised question for every model.

Accumulated queues

Add NS + EW queues
after each second.
Includes the final step.

+

Switching cost

0.5 × initiated switches
Safety timings remain
the same.

+

Final-queue cost

10 × cars still queued
at the planning boundary.
Added once.

$$J = \Sigma(q_{NS} + q_{EW}) + 0.5 \times \text{switches} + 10 \times \text{final queue}$$

Example: 3 cars left in the modeled final queue → +30 cost units.

Weight 10 was fixed before the rerun. A modeled queue penalty is not a direct count of completed SUMO trips.
